1 Model configuration

2 Assimilation

- Assimilation settings
- Observations
- Ensemble generation
- First results

3 Metrics definition

Model description

Square-box (SQB) configuration of the NEMO model:
a square and 5000 m deep flat bottom ocean at mid latitude

- domain: $24^{\circ} - 44^{\circ}$ N, $30^{\circ} - 60^{\circ}$ W
- horizontal resolution: $\frac{1}{4}^{\circ}$
- vertical levels: 11 levels between ~ 152 m and 4613 m in depth
- time integration: a leap frog scheme with time step 900 s
- calendar: 30 days per month (360 days/year)
- spin up time: 40 years

<http://www-meom.hmg.inpg.fr/Web/Projets/SANGOMA/Benchmarks/MediumCase>

Model state vector

17 variables:

| Previous time (<i>b</i> : before) | Current time (<i>n</i> : now) | Variable description | Dimension |
|---------------------------------------|-----------------------------------|-----------------------------------|-----------|
| gcx_b | gcx | ? | 2 |
| u_b | u_n | zonal velocity | 3 |
| v_b | v_n | meridional velocity | 3 |
| t_b | t_n | temperature | 3 |
| s_b | s_n | salinity | 3 |
| rot_b | rot_n | rotational of horizontal velocity | 3 |
| $hdiv_b$ | $hdiv_n$ | divergence of horizontal velocity | 3 |
| ssh_b | ssh_n | sea surface height | 2 |
| | $rhop$ | ? | 3 |

Assimilation settings

- Timing parameters:
 - analysis frequency: 2 days
 - duration: one year (360 days)

- Assimilation tool:

Ocean Assimilation Kit (OAK)

http://modb.oce.ulg.ac.be/mediawiki/index.php/Ocean_Assimilation_Kit

- Assimilation scheme:

local assimilation (water column by water column)

Observation generation

- Truth: model output of the year 75 from spin up
- Observations = truth + spatially uncorrelated Gaussian noise with given standard deviation (σ)
- Observation types: sea surface height (SSH) and temperature

① SSH:

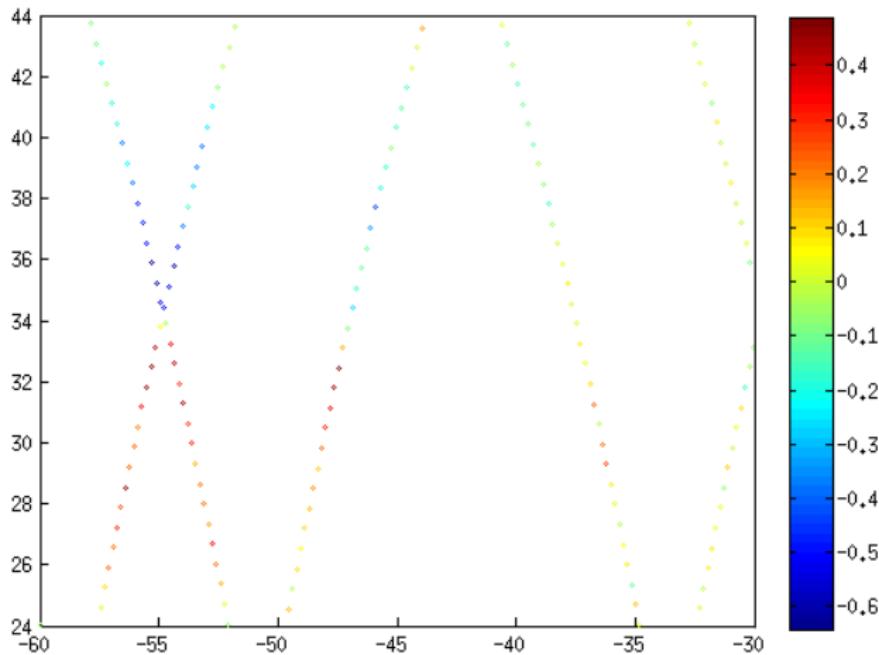

- $\sigma = 6 \text{ cm}$
- observation grid: simulation of satellite track (ENVISAT, Jason-1)

② temperature

- $\sigma = 0.3^\circ$
- observation grid: simulation of ARGO profile, average spacing $3^\circ \times 3^\circ$

Sea surface height (m)

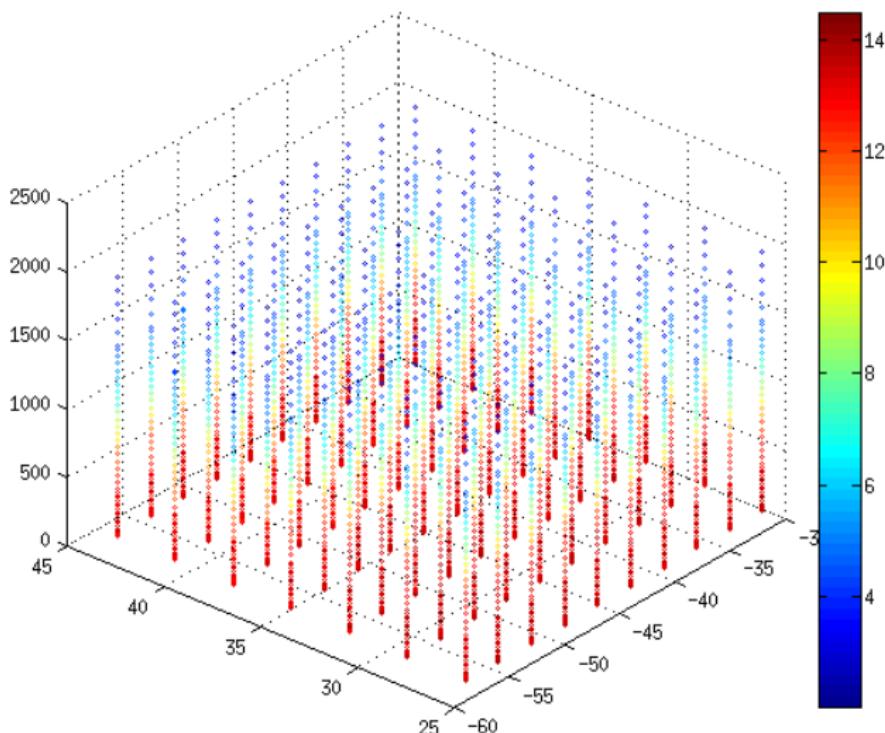

ENVISAT, 2009-01-01

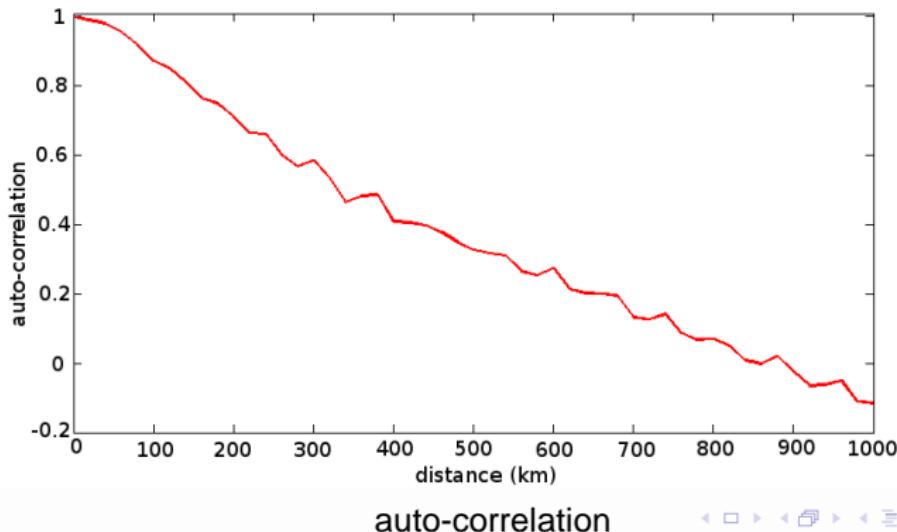

Temperature (°)

2009-01-01

Observation localization

- Observation weight function: $\exp\left(-\frac{r^2}{d^2}\right)$
(d : correlation length, r : distance from the considered water column)
- Localization length-scale (correlation length): 250 km
- Maximum correlation length: 2500 km

Ensemble generation

- 100 members:
A 10 years interval, years 41 - 50 (far away from the truth) of the free model simulation with output every 30 days is used to initialize the assimilation experiment (the last 100 outputs).
- 40 members:
Use SVD truncation to generate 40 ensemble members from the initial 100 members.
Normalization norm:
 - sum of barotropic potential energy and available potential energy (Barth et al. 2007)
 - volume and sample averaged variance (Lermusiaux et al. 1999)
 - ?

Which one to take?

Assimilation setups

3 cases:

- ① ENVISAT SSH + temperature, 100 ensemble members
(reference case)
- ② ENVISAT, Jason-1 SSH + temperature, 100 ensemble members
- ③ ENVISAT SSH + temperature, 40 ensemble members

Truth & Analysis (SSH)

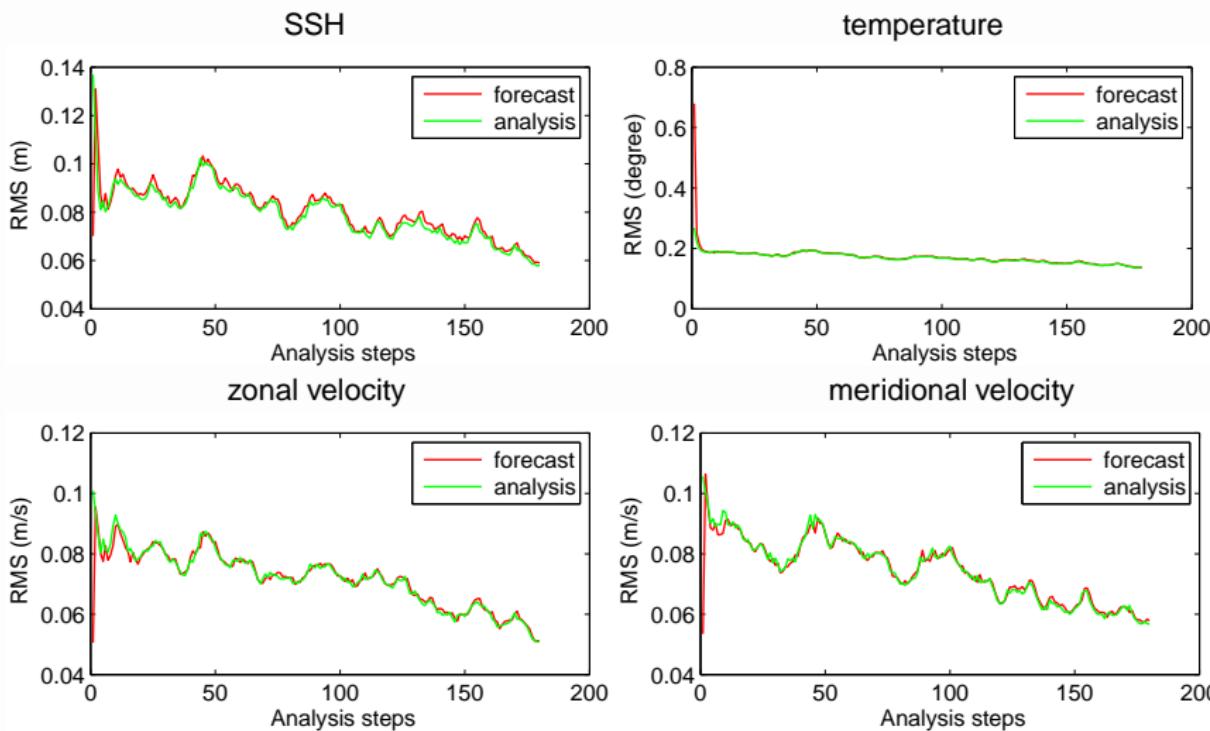

truth

analysis

snapshot every 3 steps

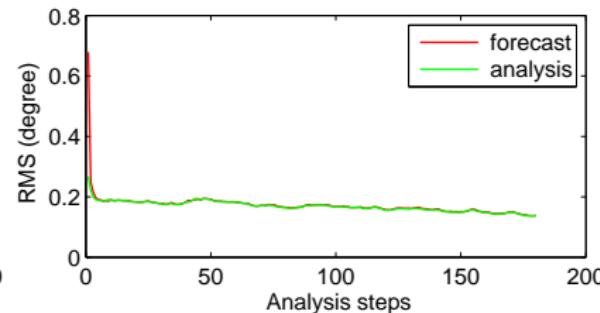

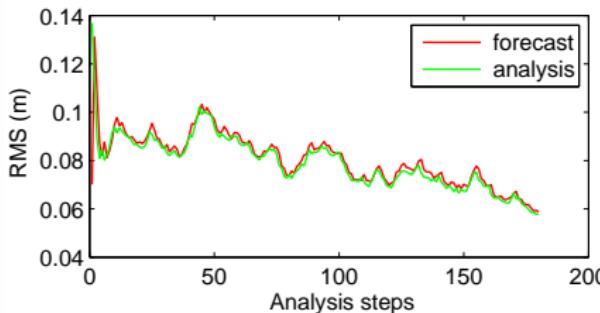

RMS: ensemble mean - truth

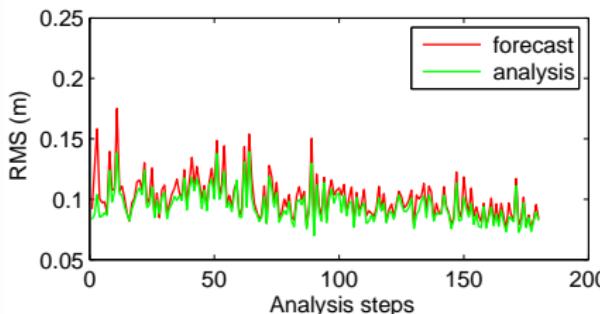

RMS: ensemble mean - truth - observation

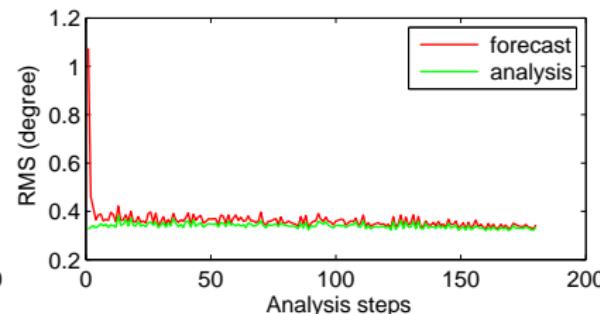

- Ensemble mean - truth

- Ensemble mean - observation

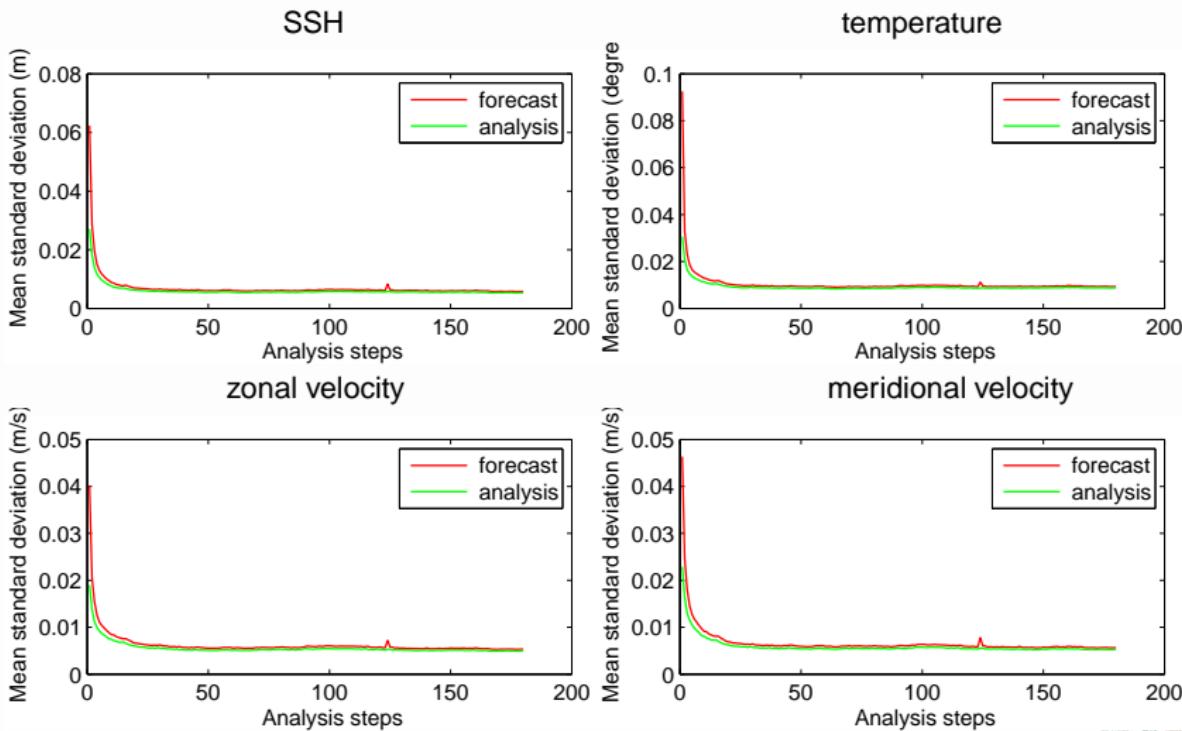

SSH

temperature

Ensemble spread

Ensemble spread (SSH)

forecast

analysis

snapshot every 3 steps

Metrics

Scores: reliability & resolution

Which parameters to take?

- RMS and bias of the ensemble mean
- Ensemble standard deviation
- Rank histogram
- Continuous ranked probability score (CRPS)
- ...
